

Overall Narrative

1. Oil & Gas is an expensive high stakes business. Every decision, every risk, every vulnerability, every mistake can compound.

This slide will state $\rightarrow$ High level numbers.

Eg 1 well $\rightarrow$ 200-500 Cr ; 1 refinery TV $\rightarrow$ Billions ; 1 wrong bidding Billions

1 day Eg $\rightarrow$ — — ; 1 lost day is a refinery 25-100 Cr

I will state the obvious.

This slide will build a case for microservices & as per my understanding Agents are microservices.

The Case: What Causes the Value Loss? $\rightarrow$ The Swiss Cheese Model.

The Value is lost to the small vulnerabilities gaps, mistakes that compound. These are like the holes in the Swiss Emmental Cheese. Since multiple systems are working in tandem, the small mistakes, delays, inefficiencies are only visible when a major event happens.

The aim is to plug the holes in that Emmental Cheese.

Slide 3

This slide will give the main Categories in which Value is lost.
This will again make the case that there are these micro events.

Ideally there should be HECE buckets that generalises the Categories.

Eg. 1. NPT loss due to log bls event and action. Observed in operations that need
Action
Real-time ~~Analysis~~ can be observed in activities; Drilling; Other operations.

2. Human time lost in low value tasks.

↳ Every Knowledge workers spends 60% of time to do work about
work.

Eg: Making Reports; Debriefs; Data Reengineering

3. Disconnected Data Silos & Systems

→ (The data is 1. Not connected 2. Not readily accessible.
3. Too large to be optimally stored by human mind.

Each of these micro events has a cascading effect on the P&L of an organisation
& overall risk & resilience profile.

I feel this slide can introduce Modelers & workflows. The micro vulnerabilities exist

Slide 4 : The Examples of High Vulnerabilities.

Petrophysicist

- Spends 2-3 hours on splitting a well. A work that is a necessary evil but doesn't bring in high value

Exploration Geologist

- Connects different data sources & relies on experience to take high value decisions

Production Engineer

- So basically each of these boxes have to be filled by a vulnerability; a risk; a delay.

Slide 5

Personal

Person 2

Eg
 Programmer
 Physicist
 Researcher

The idea is to identify and fix the vulnerabilities before they become a business risk or a value loss to the business

Slide

The Need

(This slide not need to state it clearly that these micro vulnerability need surgical high precision solutions. Solutions that are

- [1. Automated 2. Intelligent 3. ^{Powered} 4. Robust 5. Surgical]

So basically you see the need should stress to something that checks the boxes. They should be looking for Agentic Solutions without knowing what the word Agentic is..

features

(These can be the stars of the slide. It will be everything on Agent is. and it is also everything or ~~do~~ answer everything that maybe is a business concern.

Slide 7: The Introduction of an Agent

(This slide will introduce an Agent in a way that the organisation feels yes, this is what we needed; without even knowing that we needed it.

- Gives features & capabilities of Agents.
- Shows the Affection & Reverence.
- Says they are Surgical; deterministic; Physics backed
- It should address the fact that AI is non deterministic.
- Capable of learning Physics backed workflows.
- Plugs the holes of a Fundamental Cheese.

(This should give basic Architecture & Features

Slide 8

A Visceral Image.

A Tenga with some blocks removed; Signifying Organisational Vulnerabilities.

A Tenga where these Vulnerabilities are plugged with Agentic Humans.

An Org without Agents

An Org with Agents.

Back to think after Slide 8

Back - See what has been achieved so far

1. We have established there are problems in the business
2. The problems are not due to any obvious errors but they are there small, minor errors that cascade.
3. The need is 'Surgical', to identify and plug these holes of 'Emmental Cheese'.
4. The solution should be 'Surgical', 'Crisp', 'Governed', 'Trustable', 'managable'.
5. Agot is introduced as one of the obvious solutions
6. It has been shown that each vulnerability can exist either in workflows or workplace, which needs to be plugged
7. An image that shows Organisation with & without Agentic. This image will stick & they would want to plug their Org with Agents.

Now what's next?

Slide 9

Demo to show how one such vulnerability can be listed.

The Splicing Agent:

Problem:

Solution:

Business Value:

This will be a demo of an Agent that is ~~registered~~ built using ADX, Registered in Agent registry, exposed in Gemini Enterprise; Cloud Run.

GE deployment shows that all Agents can be managed from one Central UI and it becomes the Command Centre.

Cloud Run Deployment will show that the Agent can be called from any Surface, hence even Gemini Enterprise will not block them in their Agent's their specific

The done journey (Petrophysics) The Journey

1. Ask how many wells do I have in the North Sea. [It will tell 1 well]
2. Then ask about if they are Spliced & Show the ans.

[Also already by this point the value is coded as 'Extracts' Spend a lot of time searching thru data; if data search reduces from hours to seconds]

- The Agent will go to the ACS 'find related budgets'; as per the Authorisation of the Agent. It will only ~~get access to~~ search as per its Access Controls.
- Now Petrophysics is a visual discipline & So are a lot of other similar disciplines.

- Business Enterprise can render UIs from the same interface.
- Ask the Agent to show the ans & data.

Now it shows A2U1 that can assist in finding those UIs if needed.

- This will also give links to any services that may have the Agent being called

- The Gemini Enterprise will provide the initial links.
- Then it will also provide links to the Cloud Run application. It could have been any application that needs these Agents.

- Then show the GCS bucket that has the data. Show the user has complete visibility & control of their data, w/ its residency; access permissions.
- In the medical records, the data lives in a Software System without much visibility & control.

- Then show that the Agent can have multiple; named Gates; in the Sense it is headless.

- First show the three SaaS. Ask the Agent to splice...

Then explicitly say the Agent implements deterministic Physics based rules, Performs causal correlation over a 30-50 m window. Attaches the log when the correlation coefficient is max

The Demo Journey Continued

12/21 2.1

- Also the point is not if the Low Code/No Code approach was the right approach it is that

1. The Agent can be centrally managed.
2. Can be called from ~~and~~ multiple devices
3. Can implement deterministic physics based rules.
4. Has proper governance.

The Show the ACS bucket → to show the ~~core~~ Spliced well.

The Show Bypass for governance.

Part 1c → After Demo

Agent Architecture

Show Agent Architecture.

Say you can imagine hundreds of such agents in one org that can improve efficiency, increase speed, decision accuracy & making the organisation more profitable & future proof.

Goal II

No Ash: No Active for Business

Case In Point

- Identifying such Agonic vs Cases in the Organization through a discovery workshop.
- Expose those entities; identify those missed opportunities.
- This will become the map of Risk & Operations & we will plug these gaps to make the business more profitable & high growth

Feb 12

Discussion & Next Steps
